

(a) Both quantities rise, monotonically, on the SAME three runs
rank statistic R3 — the column these logs' own `final\_eff\_rank=` line reports

(b) The direction survives the choice of rank statistic
canonical R1 — the statistic §4.1's exported-block floor is measured in

(c) the rank track

(d) the collapse measure

ONE SEED PER LEVEL. The rank change is $\times 1.854$ under R3 and $\times 1.940$ under the canonical statistic — both CLEAR this block's own step-400 floors of $\times 1.449$ and $\times 1.570$, the grey bands in (a) and (b). §4.1's $\times 3.295$ is a DIFFERENT BLOCK and a different arm and is not drawn here. THE MONOTONICITY AND THE CO-MEASURED COSINE CARRY THIS RESULT, NOT THE MAGNITUDE OF THE RANK CHANGE, and no sentence about it may be quoted as though they did — least of all the pass.

F9. Draft section 4.9a. Raising the covariance-decorrelation weight raises effective rank monotonically across three levels while the RNA-view patient-to-patient mutual cosine - a direct measurement of the condition rank exists to detect - rises monotonically WITH it, co-measured on the identical runs and printed on the same log lines. At 0.8696 the RNA-view states of different patients are nearly the same vector, and rank moves the wrong way as that worsens. This is a stronger dissociation than draft section 4.9's instances for two reasons about the SHAPE of the evidence rather than its size: it is monotone across three levels rather than a single contrast, and the contradicting quantity is co-measured rather than inferred from a downstream readout in another table. The floor drawn in (a) and (b) is THIS BLOCK'S OWN, per statistic, at the reading step these runs are quoted at: five same-seed repeats of each of two arms on the fixed held-out probe at step 400 give 1.4489x under R3 and 1.5702x under canonical R1, and the sweep clears both. Draft section 4.1's 3.295x is canonical R1 on the residualised EXPORTED wsi_biology block of a DIFFERENT ARM at 40 epochs; it never licensed this comparison and is deliberately not drawn - an earlier version of this figure drew it and printed BOTH INSIDE, which is the block mismatch draft section 4.1a exists to catch. Clearing is not what the figure claims: at one seed per level a magnitude that clears an $n = 5$ floor is not evidence of a dose-response, and the floor itself is $n = 5$ per arm at one seed on one stack. Draft section 4.1a rows 54-55. It also carries a correction: "feature_decorrelation is defective" was CONDITIONAL ON A QUERY-WRITTEN QUEUE. Without a momentum key encoder the same term aggravated the collapse (1.59 against 2.17 at step 250, draft section 5.1 instance 3); with one it raises rank. Every claim this project makes about that term needs "in the absence of a momentum key encoder" attached. Statistic and block are named on every axis, and R3 and the canonical statistic occupy separate panels because binding constraint 1 forbids two rank statistics on one axis.
